

Supporting An Architecture-Based Approach to Systems Modeling

John Georgas
Institute for Software Research
University of California, Irvine
Presented at GSAW 2003

Outline

- **Context and Background**
- Techniques and Tools
- Goals and Results
- Open Questions
- Conclusions and Future Direction

Systems Modeling is Difficult

■ Why?

- Usually, there is a large number of different groups involved in the design of any given system.
- Each group operates in a heterogeneous domain, and may approach their work in different ways.
- The work of one group may have far-reaching effects on the work of other groups.

■ Space exploration mission design is an excellent example.

- Example groups/domains
 - Control software.
 - Hardware design and construction.
 - Mission cost analysis.

Incongruent modeling techniques, and implicit representations of dependencies and connections are not sufficient.

Addressing Difficulties in Mission Modeling

- CCSDS Architecture Working Group
 - Conceptual goal: Develop overall CCSDS architectural concepts, and establish standard modeling techniques to be used by such organizations as JPL.
 - Practical goal: Provide a designer toolkit supporting and automating these techniques.
- In support of this practical goal...
 - Use ISR/UCI *software architecture* modeling concepts, techniques, and tools to support *mission design* – and, more broadly, *systems modeling*.

Models, even well-defined ones, are of limited use without a firm connection to the realization of what they model.

Outline

- Context and Background
- **Techniques and Tools**
- Goals and Results
- Open Questions
- Conclusions and Future Direction

xADL

- An extensible, modular architecture description language based on XML.
 - Initially, intended for software architecture, so...
 - **Components**, and **connectors** at the forefront.
 - But...
 - Completely modular and extensible using standard XML schemas.
- Why xADL?
 - Established “pedigree” of usefulness.
 - Extensible and modular.
 - Extensive commercial tool support for XML.

Other Tools

■ Apigen

- An automated data binding library generator using the XML schema.

■ ArchStudio 3.0

- A component-based, extensible, software architecture development environment.

■ ArchEdit

- A generic, context-aware, lightweight editor.

■ Critics

- Design-time analysis framework and tools.

■ Why?

- A collection of “free” tools and development framework.
- Context-aware tools that automatically adjust to different models.
 - Quick experimentation with different modeling decisions, essential in this emerging domain.

Though initially intended for software architectures, these tools and techniques are domain independent.

Outline

- Context and Background
- Techniques and Tools
- **Goals and Results**
- Open Questions
- Conclusions and Future Direction

Goals of This Effort

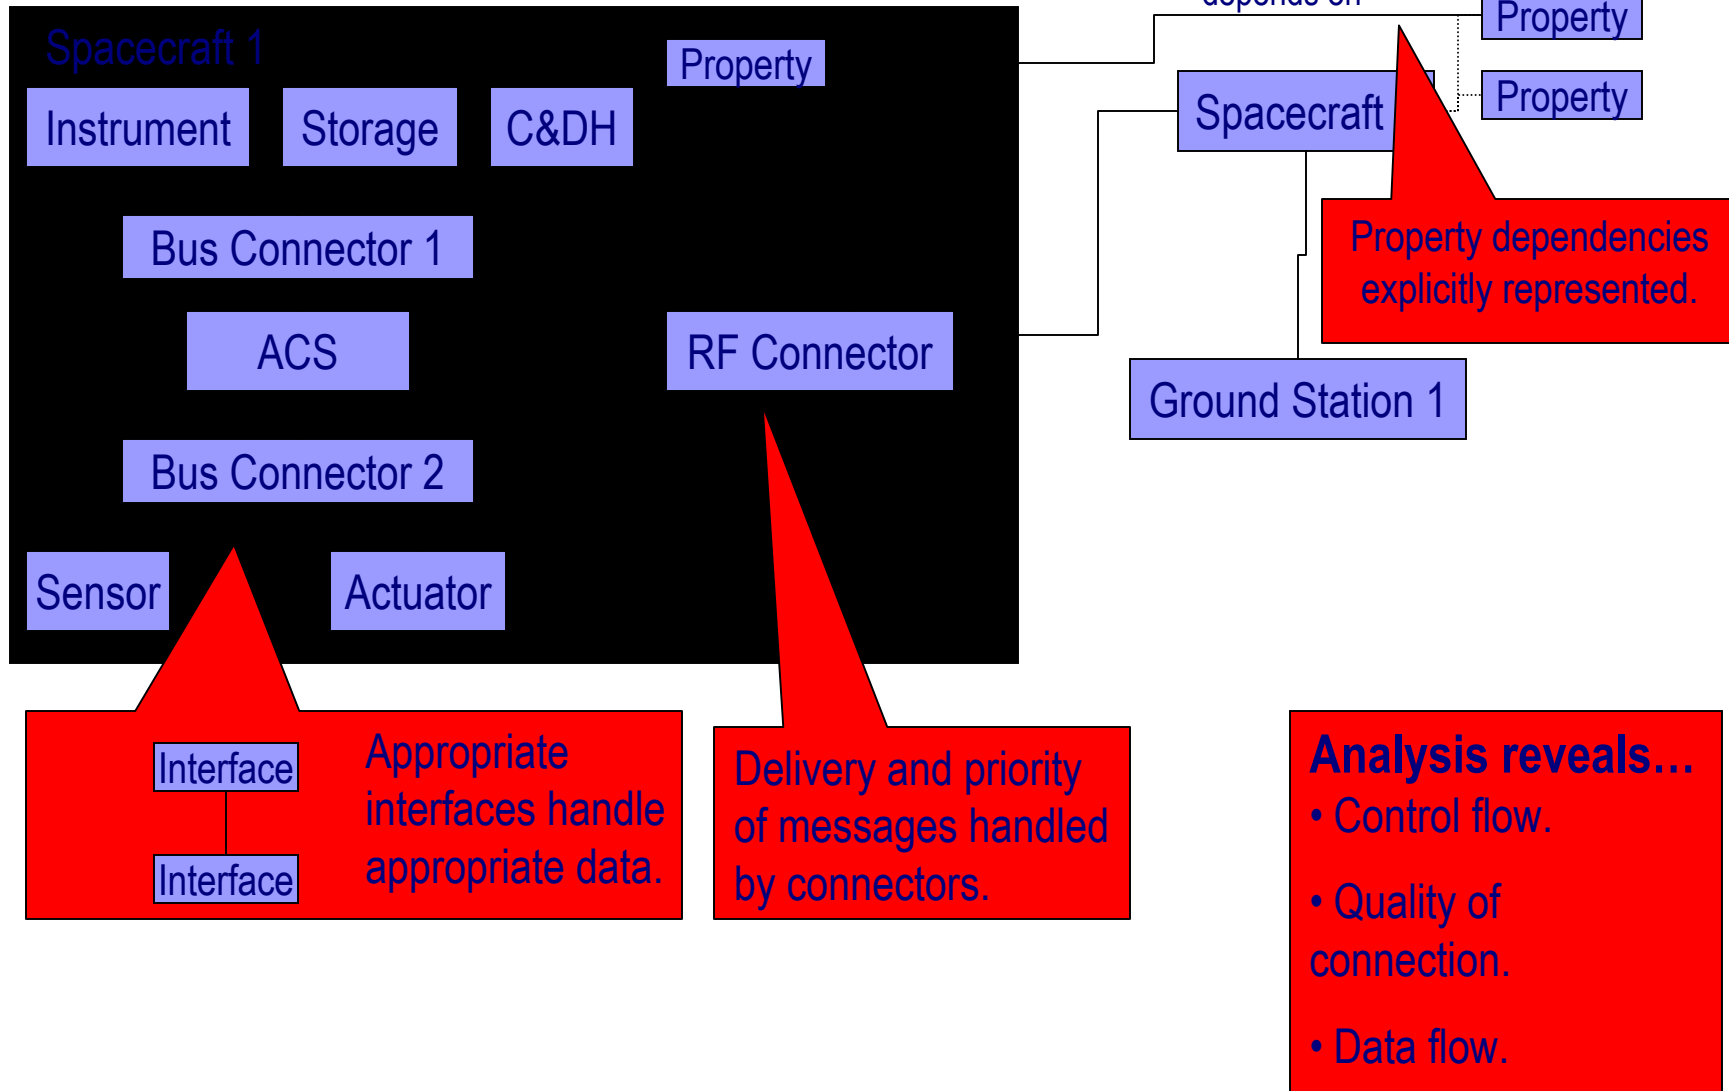

- Determine the usefulness of the ISR/UCI techniques for mission modeling.
 - Task 1
 - Create models (ontologies) of various mission aspects.
 - Task 2
 - Model these as extensions of xADL 2.0.
 - Task 3
 - Explore the usefulness of the base xADL tools.
 - Task 4
 - Provide mission-modeling specific support with tool enhancements.
 - Task 5
 - Provide a simulation framework.

Task 1: Model Creation

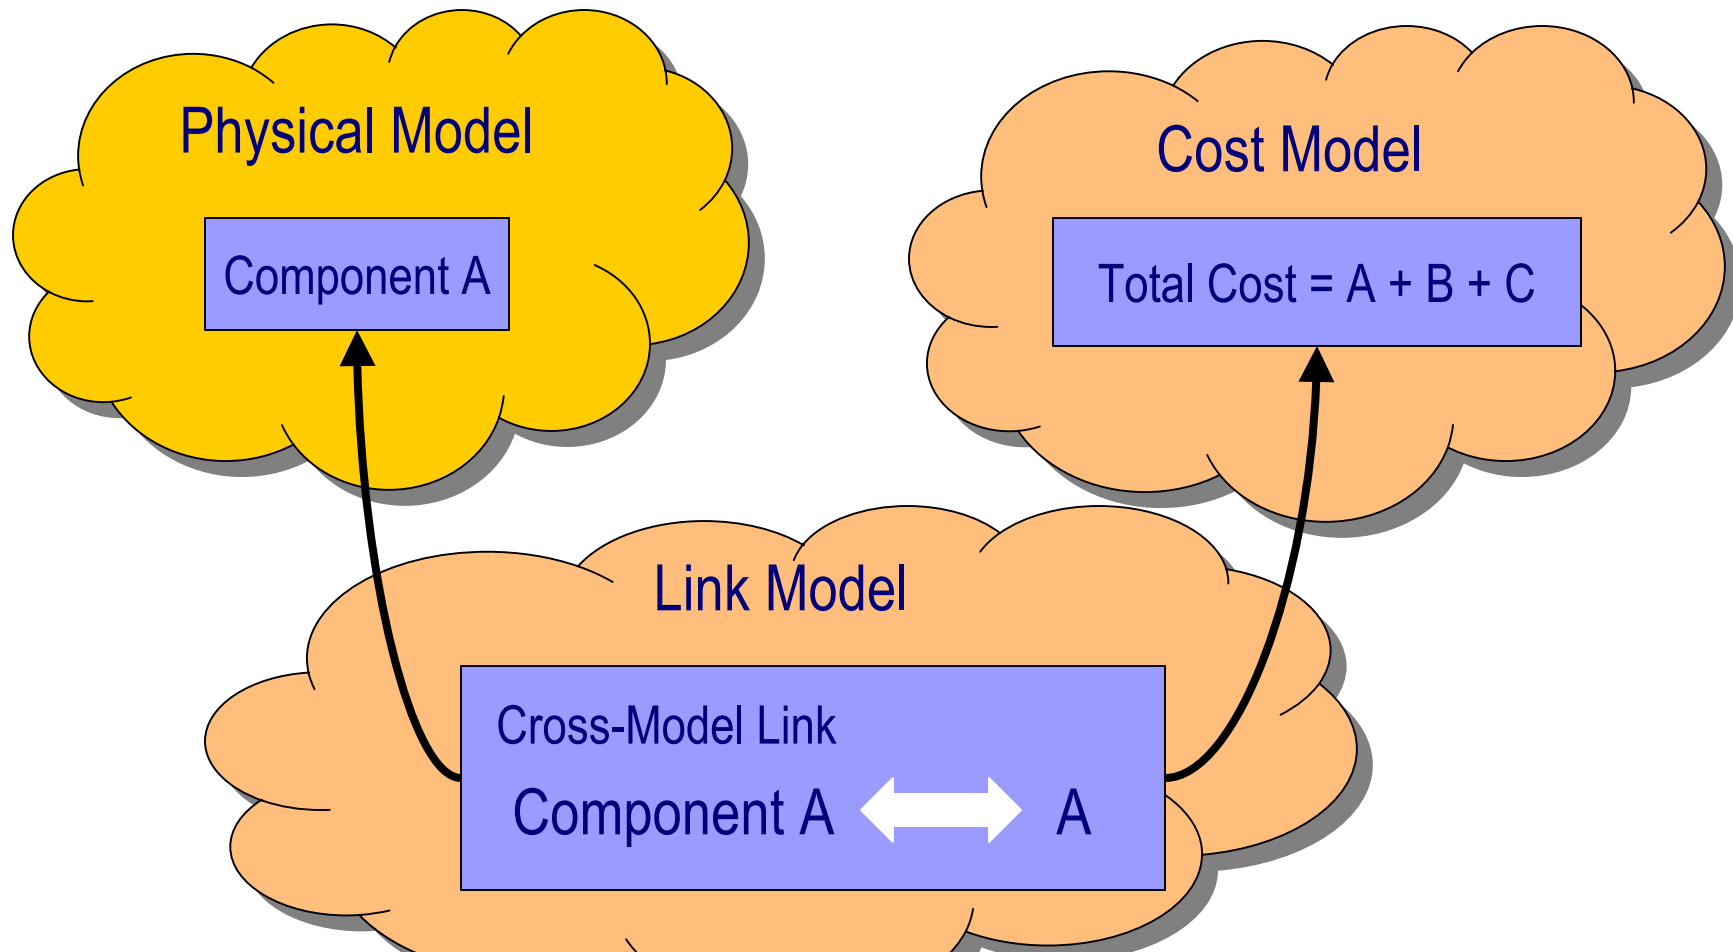

- These models were primarily intended for experimental purposes.
 - Not intended to be definitive.
- Areas modeled included cost analysis, communications connectivity, and control software.

Bringing out **connections** between elements from different **domains** of mission design was a major focus.

Example: Communications Connectivity

Cross-Model Relationships

This link is treated as a **first-class** entity.

Task 2: xADL Representation

- Models defined through the use of XML schemas.

```
<xsd:complexType name="MissionStructure">
  <xsd:sequence>
    <xsd:element name="component" type="MissionComponent"/>
    <xsd:element name="connector" type="MissionConnector"/>
    ...
  </xsd:sequence>
  <xsd:attribute name="id" type="archinstance:Identifier"/>
</xsd:complexType>
```

- By using data-binding libraries, architectures can be maintained and manipulated through simple function calls.

```
xarch.add(xArchObjRef, "Component", component);
String id = (String)xarch.get(source, "Id");
```

Other Concepts Represented

- The ability to specify sub-architectures, and compose models hierarchically.
- Associate properties with components as well as being able to specify derived properties.
- Versioning of all model entities, and the maintenance of version trees.
- Included both instance and type information for promoting reuse.
- The ability to specify mission *temporal evolution* based on environmental properties.

Task 3: Using the Generic Tools

■ ArchEdit

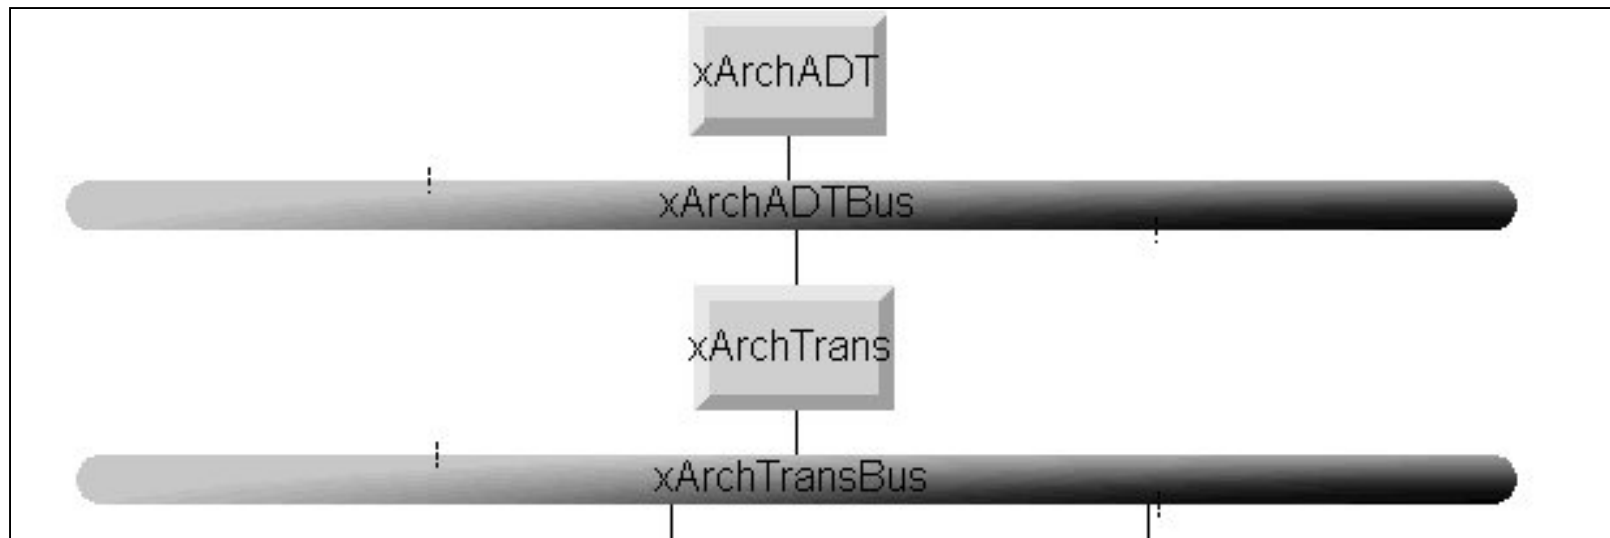

- The editor is context-aware, meaning it can be used with any provided schema with no need for modification.
- A “free,” high-fidelity editor with every model.

Graphical Depictions

■ Microsoft Visio

- Integrated into the ArchStudio 3.0 tool suite.
- Event-based coordination between all ArchStudio components, so that the view you see is faithful to the state of the model.
- A “cheap,” high-fidelity graphical editor.
 - The association between modeling elements and their graphical depictions must be made.

Task 4: Tool Enhancements

- ArchStudio 3.0 Critic Framework
 - Critics, Critic Manager, Critic GUI.
 - Design-time analysis with problem identification and suggested fixes.
 - Extensibility through the addition of custom critic components.
 - Development framework facilitates this.
- Designed and implemented custom *mission modeling* Critics.
 - Design sanity-checking; compliance with model semantics not explicitly represented.
 - Cross-model link maintenance.
 - Presentation of cross-model links, and notifications driven by identified dependencies.
- Tool customization is inevitable!
 - Semantics are specific to a given domain.
- But, this is a relatively “inexpensive” analysis tool framework.

Task 5: Simulations with Ptolemy

- A modeling and simulation framework from UC Berkeley, intended for embedded systems.
 - Java libraries covering a variety of domains.
 - XML based file storage (actually, MoML).
- XML is the key for an initial integration attempt.
 - Custom ArchStudio 3.0 “translator” component that creates the basic framework of a Ptolemy simulation.
 - Significant editing must take place with the Ptolemy tools, as semantics of interaction must be represented.

Outline

- Context and Background
- Techniques and Tools
- Goals and Results
- **Open Questions**
- Conclusions and Future Direction

Open Questions and Challenges

- What is the utility of models without formalisms?
- What should a model that incorporates many varied aspects of a mission look like?
- What should the design environment be like?
- How do we efficiently simulate missions once a formal model of them has been defined?

Conclusions

- Lots of open questions!
- We've shown that xADL, though a *software engineering* technology, is general enough to apply well to the mission modeling domain and *systems modeling* in general.
- A formal **syntactic base** can be provided to any set of architectural concepts making any model more than just a collection of graphs.
- Significant **semantic capabilities** can be enabled such as automated design-time sanity checking and dependency management.

Extra Slides

A Quick Primer on Architecture

- The structure of a system's components and how they're connected.
- Behavior as collaborations between these components.
- Constraints on particular details of compositions usually loosely enforced by architectural styles.

Difficulties Abstracted

- Complexity.
- Visibility.
- Changeability.
- Inter-component dependencies.

What's the best way to address these difficulties?

Utility: Boxes and Arrows Only?

- An example: “Pure” UML.
 - Essentially nothing more than imposed conventions on a set of graphical widgets.
- Is it useful?
 - Helps the designer achieve clarity of vision.
 - Allows for communication of ideas from a common context.
- **But**,
 - How close is the implemented system to the model?
- How do we achieve a tight coupling of implementation and model?
 - In the software engineering world, one can generate source code from formally specified UML models.

What does this “generative” approach mean in the mission modeling world? Is the utility of a formal approach limited to design-time?

Open Questions!

- What is the utility of models without formalisms?
- **What should a model that incorporates many varied aspects of a mission look like?**
- What should the design environment look like?
- How do we simulate missions once a formal model of them has been defined?

Model: Unified

■ Unified Model

- Central representation with various views.

■ Why?

- Coordination
- Version management

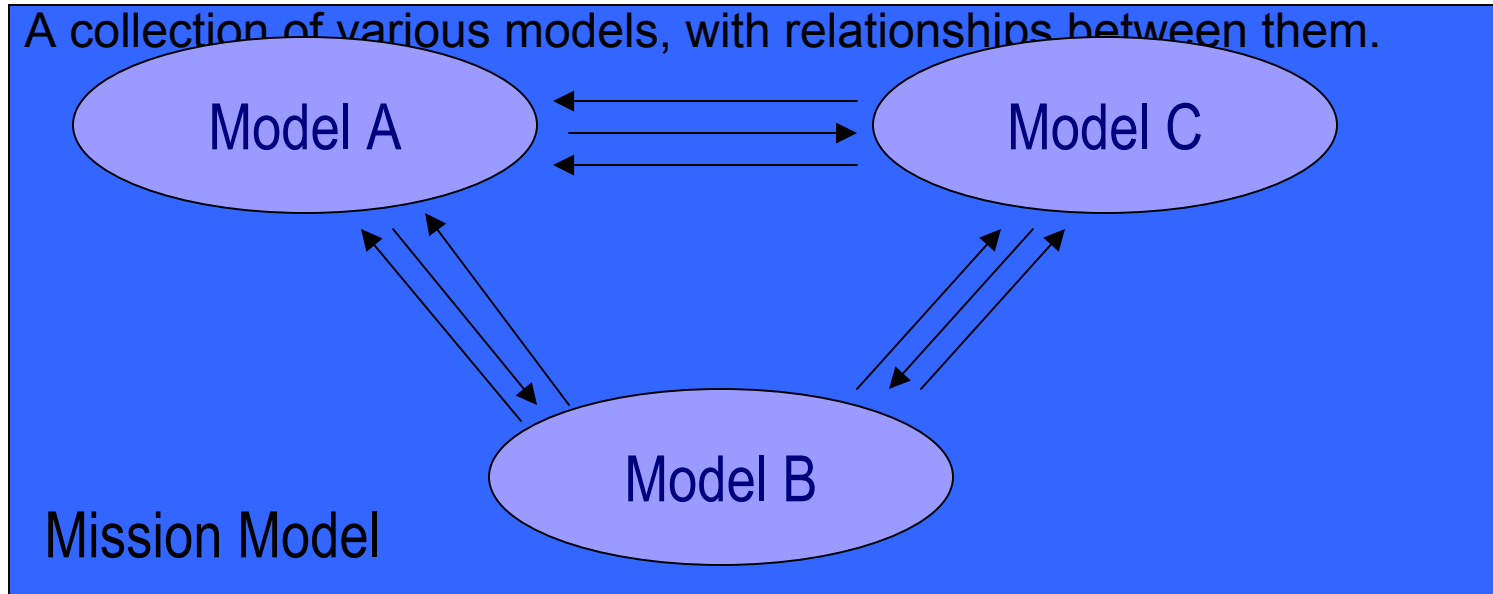

■ Why not?

- View extractor trust
- Visibility of changes

Model: Not!

■ Decentralized Model

- A collection of various models, with relationships between them.

■ Why?

- Version management.
- Clarity of each model.

■ Why not?

- Cross model knowledge.
- Large number of links.

Model: Are They The Same?

Questions: Which one is better for mission design? Is a central model even possible?

Open Questions!

- What is the utility of models without formalisms?
- What should a model that incorporates many varied aspects of a mission look like?
- **What should the design environment look like?**
- How do we simulate missions once a formal model of them has been defined?

Design Environment: Is Change Good?

■ The Big Question

- Do we replace what is used with tools designed for the model, or do we adapt to the tools being used?

Custom Tool

■ Why?

- Little changes for the users other than enhancements.

■ Why Not?

- Some semantics and model-enabled capabilities may be lost.

■ Why?

- Fully functional with preservation of semantics.

■ Why Not?

- Costly to build.
- Resistance to adoption.

Questions: Do we change the way people do work? What if it buys us a lot?

Open Questions!

- What is the utility of models without formalisms?
- What should a model that incorporates many varied aspects of a mission look like?
- What should the design environment look like?
- **How do we simulate missions once a formal model of them has been defined?**

Simulation: Let's Build It!

- What do we need to do...
 - Define and code a model of a mission environment.
 - Define and code the behavior of an element within this environment.
 - Define and code interactions between elements, and between elements and their environment.
 - Capture results, and organize them in an understandable way.
- Why?
 - Domain knowledge.
 - Expressiveness.
 - We know how to code.
- Why not?
 - A lot of development.

Simulation: Let's Reuse It!

- What do we need to do...
 - Define a mapping from our model to the simulation framework.
- But,
 - Is the simulation framework domain independent?
 - If not, how do we deal with the semantics of the simulation framework?
 - Can we automate the mapping process?
 - If not, we'll have to "code" anyway, but this time in what may be an unfamiliar environment.
- Why?
 - Reuse of the framework.
- Why Not?
 - See questions.

Question: Which one is the best balance between cost and expressiveness?

Where To Now With This Approach?

- A clear vision of a desired model must be established and accepted.
- A formal definition of this model can then be created using xADL.
- With the formal definition in place, a basis for a mission design environment is in place due to the generality of the xADL tools and ArchStudio 3.0.
 - An easy way to maintain model-definition documents.
 - A “free” low level editor.
 - A framework for a modular design environment is already in place.
- Custom tool design
 - A front-end graphical editor that has a bit of domain knowledge.
 - Model maintenance and analysis tools.
 - Tools that connect the mission model with the actual implementation.
